

This sheet is to show how to create, a new Droplet, a new sub-domain, and point the sub-domain to the droplet.

Log into Digital Ocean: <https://cloud.digitalocean.com/droplets>
This droplet is for a dynamic page. It will need an operating system and a server.

Choose an operating system:
Ubuntu

The droplet will need software. Digital Ocean provides a number of options. For now, we'll choose LAMP:
LAMP stands for:
LINUX Operating System
APACHE Web Server
MySQL Database
PHP
[http://en.wikipedia.org/wiki/LAMP_\(software_bundle\)](http://en.wikipedia.org/wiki/LAMP_(software_bundle))

Choose a size:

Choose a region:

Add an SSH key:
You can make an SSH key for your computer and use that.

Choose a host name:
Make the host name match the sub-domain. That way it will be easier to remember which things go together.

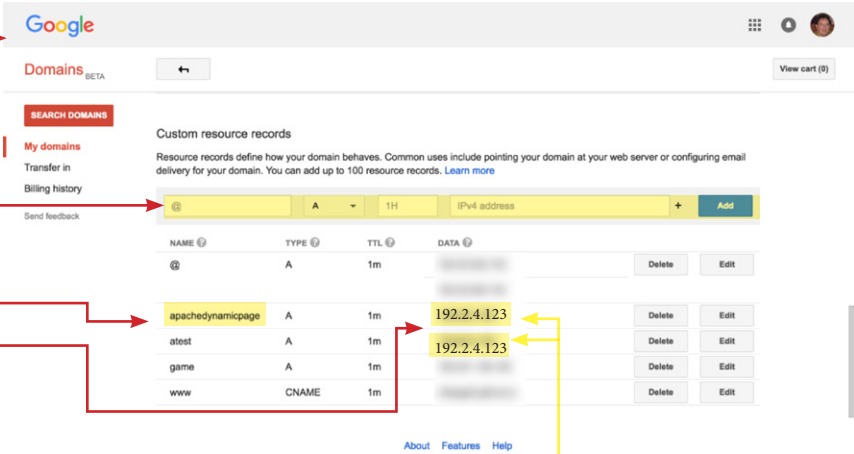

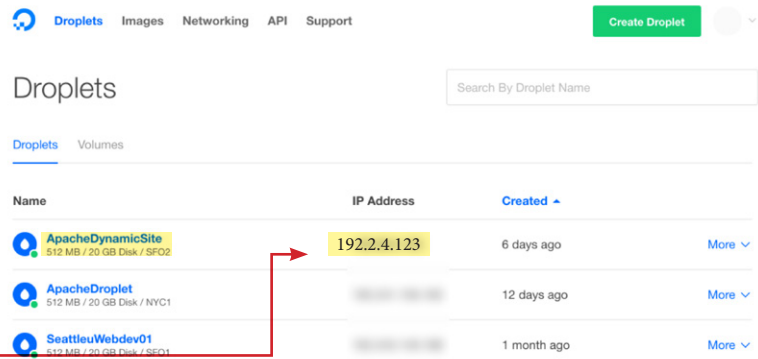

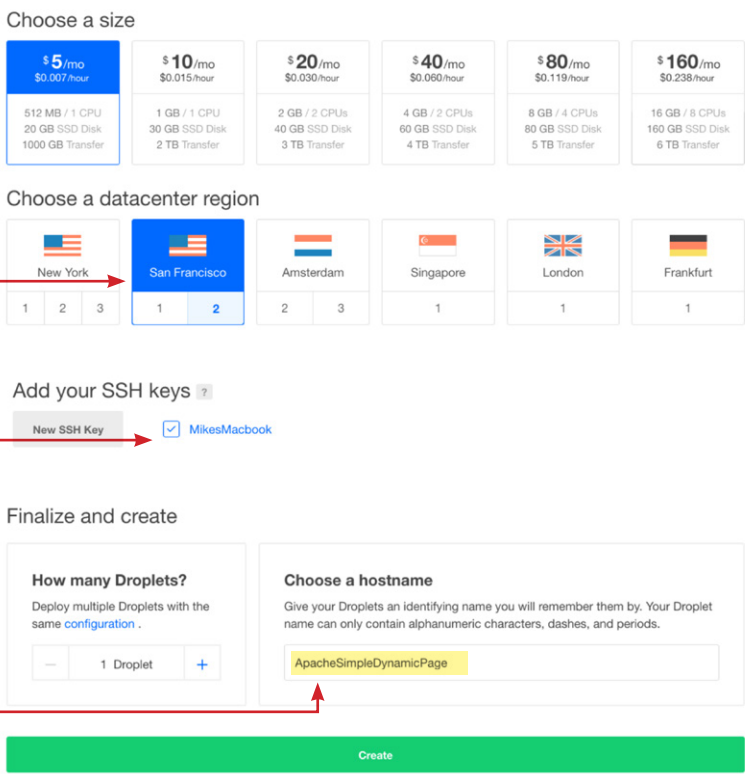

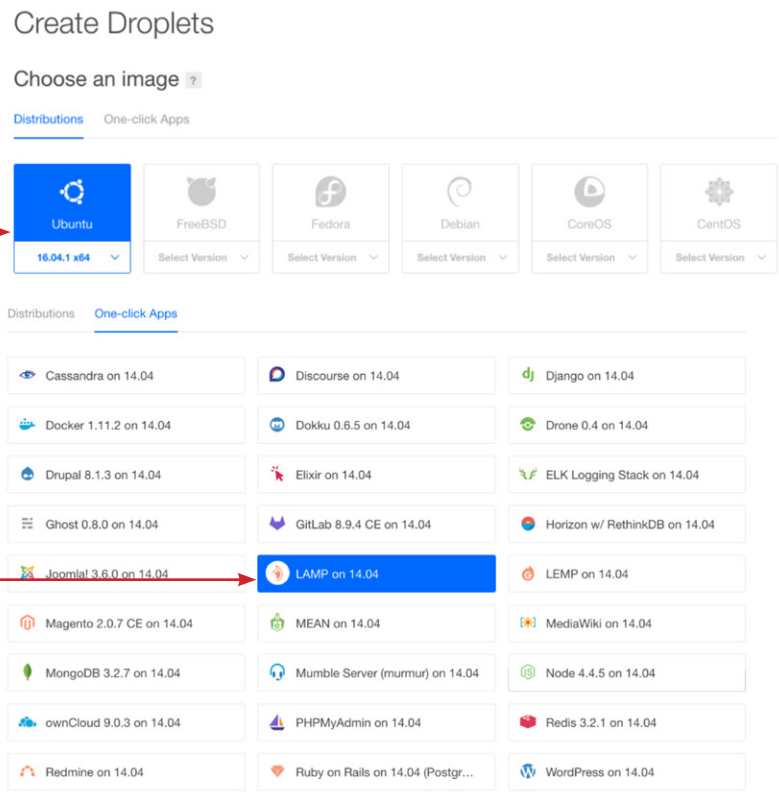

Make note of the ip address of the Droplet.
This will be pasted into the new sub-domain.

Create a sub-domain:
The original domain is made on Google.
Go to: <https://domains.google.com>

Create a new sub-domain by filling out this row.

Make the sub-domain name match the Droplet name.
Copy the Droplet ip address & paste it here.

After you have a Droplet, you can:
Create multiple directories/websites.
Just point new sub-domains to the same (Droplet) ip address.
Then, you need to configure Apache to present the new directory.

This sheet is to show how to configure Apache and Git for a new droplet.

Use a command line to connect to the droplet. The following commands will install & configure Git on the droplet. Git needs to be installed at the root level of the Droplet. When done, you can start cloning Git repositories to the droplet.

Note:

Git repos should cloned into `~/var/www/html/Name-of-repo`

In this example it will be:

`root@NameofDroplet:/var/www/html/NameofRepo`

The root in this example uses the name of the Droplet.

`root@ApacheDynamicSite:/var/www/html/wats1030-dynamic-page`

From Terminal:

Connect to the droplet:

`ssh root@ip address`

INSTALL GIT TO THE DROPLET.

`root@ApacheDynamicSite:~# sudo apt-get install git`

SET GIT ON THIS DROPLET TO USE THIS NAME.

`root@ApacheDynamicSite:~# git config --global user.name "Name"`

SET GIT ON THIS DROPLET TO USE THIS EMAIL.

`root@ApacheDynamicSite:~# git config --global user.email "email"`

CREATE SSH KEY

`root@ApacheDynamicSite:~# ssh-keygen -t rsa -b 4096 -C "email"`

CREATE SPECIFIC ID FOR SSH

`root@ApacheDynamicSite:~# eval "$(ssh-agent -s)"`

ADD ID TO THE SSH KEY

`root@ApacheDynamicSite:~# ssh-add ~/.ssh/id_rsa`

SHOW ME THE PUBLIC SSH KEY. SO I CAN PASTE IT INTO GITHUB.COM

`root@ApacheDynamicSite:~# cat ~/.ssh/id_rsa.pub`

Go to: Github.com/settings/SSH and GPG keys

Use a title that helps you remember what this key is for.

Paste the key here.

CHANGE TO WEB ROOT DIRECTORY

`root@ApacheDynamicSite:~# cd ..`

`root@ApacheDynamicSite:~# cd /var/www/html`

CLONE MY GIT FORK INTO MY DROPLET.

`root@ApacheDynamicSite:/var/www/html/wats1030-dynamic-page#`

`git clone git@github.com:GithubUserName/GithubRepo`

CHECK YOUR WORK.

`root@ApacheDynamicSite:/var/www/html/wats1030-dynamic-page# ls`

THE CLONE IS HERE!

`wats1030-dynamic-page`

Next, Configure Apache to present the info in this droplet/this directory

This exercise contains sample files. Some of these files are the website we want to present, others are used to tell Apache what to do.

COPY MOVE & RE-NAME THE DEFAULT APACHE CONFIG FILE

`cp /etc/apache2/sites-available/000-default.conf /etc/apache2/sites-available/sub-domain.domain.com.conf`

This will put the config file where Apache can find it.

OPEN OUR NEWLY CREATED CONFIG FILE AND MODIFY IT.

Change directory to: `~/etc/apache2/sites-available`

`root@ApacheDynamicSite:/etc/apache2/sites-available# less sub-domain.domain.conf`

Tell Apache your **sub-domain.domain**.

Show Apache the path to your files.

Tell Apache which file to display.

TELL APACHE, THIS IS THE DEFAULT CONFIG TO USE.

`root@ApacheDynamicSite:~# sudo a2ensite sub-domain.domain.com.conf`

RE-START APACHE

`root@ApacheDynamicSite:~# service apache2 reload`

```
root@ApacheDynamicSite:~# cat ~/.ssh/id_rsa.pub
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAQDBVGMV+yk3CeUv/qR+CFeX0yuodA+6Hz10zUxfhGU0r0

Title

Key

Begins with 'ssh-rsa', 'ssh-dss', 'ssh-ed25519', 'ecdsa-sha2-nistp256', 'ecdsa-sha2-nistp521'

Add SSH key

Re-name this to this

```
# This is a sample host config for Apache.

<VirtualHost *:80>
    # Replace with your subdomain/domain combo
    ServerName apachedynamicpage.mikegalligar.com

    # Your email address
    ServerAdmin mkgalligar@gmail.com

    # The following assumes standard Digital Ocean LAMP file structure
    DocumentRoot /var/www/html/wats1030-dynamic-page/

    # Instruct Apache to display the index.php file by default
    DirectoryIndex index.php

    ErrorLog ${APACHE_LOG_DIR}/error.log
    CustomLog ${APACHE_LOG_DIR}/access.log combined
</VirtualHost>
```
